

Sachem

Sachems are widespread and common in Alabama. They are multi-brooded, flying late spring, summer, and fall. Open, sunny, often weedy areas provide habitat. This includes yards and gardens. Males perch on low vegetation or on bare ground. Both sexes nectar from a wide variety of flowers.

- Sexually dimorphic. Males have a very prominent stigma. They are brighter in general but ventral markings are not as strong as females. Females are browner and typically have a strong chevron pattern on ventral hindwings.
- Sachems, particularly females, are extremely variable in base color and markings. Some are very brown while others are golden; some are highly patterned while others are plainer.
- May be confused with Fiery Skippers and Whirlabouts. Dorsally, male Sachems have a stand-alone prominent, squared stigma. Female Sachems have two glassy spots on forewing with a dark patch attached to the base of the larger one. Ventrally, males and females lack small dark dots (Fiery) and large dark spots (Whirlabout). Also, look for brownish patch at center of the hindwing trailing margin.

Sachem

Dorsal Male

Very prominent dark stigma*

Tawny orange wing color with brown along the wing margins

Tawny orange with dark branching veins*
